

CUSTOMER SUPPORT TICKET ANALYTICS

BPMN 2.0

AS-IS Diagram

This diagram captures the current, fully manual ticket-handling flow. A customer submits a ticket, the system logs it, and it enters a single shared queue to wait until an agent is available. The agent provides a first response and works the ticket; an exclusive gateway checks whether it's resolved and loops it back to "Agent Works on Ticket" if not. Once closed, a second gateway checks whether the ticket is later reopened (looping back into agent work if so), and only then does a third gateway decide whether a CSAT survey is sent at all. That optional, inconsistent step is the process-level reason only ~31% of tickets in the dataset carry a CSAT score. Nowhere in the flow is there queue prioritization, SLA tracking, or a reporting layer. It's a flat, sequential, agent-driven process with no visibility for management.

TO-BE Diagram

This diagram deliberately keeps the same manual steps (logging, manual assignment across the five queues, manual priority tagging, agent response and resolution, and the same

resolved/reopened/CSAT gateways) since process automation (auto-routing, SLA workflows, real-time monitoring) is explicitly out of scope for this BRD. The actual improvement is the new Management/Reporting lane: a historical extract of the ticket data now feeds a centralized operational dashboard covering volume and trend, channel/queue breakdown, first-response and resolution time, open/unresolved backlog, reopened rate, and CSAT (including its relationship to response speed), filterable by date, channel, queue, and priority.
